

Source: this study, scripts/memo_evpi_control.py. (a) ae.agent.decisions.evpi at $n_{\text{outer}}=256$, $n_{\text{inner}}=256$, seeds 11, 23, 37, 53, 71, 97. (b) same estimator at seed 11, with a dummy input drawn from a prior and discarded by the value function. The estimator forms its own baseline per call (sd 0.678 MUSD across the six seeds) and clamps the difference at zero, so baseline noise appears as one-sided positive EVPI. Switch fraction was exactly 0.000 for all nine real parameters at every seed tested.
